Basic Complex Integration

Introduction

Complex variable techniques have been used in a wide variety of areas of engineering. This has been particularly true in areas such as electromagnetic field theory, fluid dynamics, aerodynamics and elasticity. With the rapid developments in computer technology and the consequential use of sophisticated algorithms for analysis and design in engineering there has been, in recent years, less emphasis on the use of complex variable techniques and a shift towards numerical techniques applied directly to the underlying full partial differential equations model of the situation. However it is useful to have an analytical solution, possibly for an idealized model in order to develop a better understanding of the solution and to develop confidence in numerical estimates for the solution of more sophisticated models.

The design of aerofoil sections for aircraft is an area where the theory was developed using complex variable techniques. Throughout engineering, transforms defined as complex integrals in one form or another play a major role in analysis and design. The use of complex variable techniques allows us to develop criteria for the stability of systems.

Prerequisites

Before starting this Section you should . . .

1. be able to carry out integration of simple real-valued functions
2. be familiar with the basic ideas of functions of a complex variable as in section 26.1
3. be familiar with line integrals

Learning Outcomes

After completing this Section you should be able to . . .

✓ understand the concept of complex integrals
1. Complex integrals

If $f(z)$ is a single-valued, continuous function in some region $R$ in the complex plane then we define the integral of $f(z)$ along a path $C$ in $R$ as (see Figure 1)

$$\int_C f(z) \, dz = \int_C (u + iv)(dx + i\, dy).$$

Figure 1

Here we have written $f(z)$ and $dz$ in real and imaginary parts:

$$f(z) = u + iv \quad \text{and} \quad dz = dx + i\, dy.$$  

Then we can separate the integral into real and imaginary parts as

$$\int_C f(z)dz = \int_C (u\, dx - v\, dy) + i \int_C (v\, dx + u\, dy).$$  

We often interpret real integrals in terms of area; now we define complex integrals in terms of line integrals over paths in the complex plane. The line integrals are evaluated as described in Workbook 29.
**Example** Obtain the complex integral:

\[ \int_C z \, dz \]

where \( C \) is the straight line path from \( z = 1 + i \) to \( z = 3 + i \). See Figure 2.

![Figure 2](image)

**Solution**

Here, since \( y \) is constant (\( y = 1 \)) along the given path then \( z = x + i \), implying that \( u = x \) and \( v = 1 \). Also \( dy = 0 \).

Therefore,

\[
\int_C z \, dz = \int_C (u \, dx - v \, dy) + i \int_C (v \, dx + u \, dy)
\]

\[
= \int_1^3 x \, dx + i \int_1^3 1 \, dx
\]

\[
= \left[ \frac{x^2}{2} \right]_1^3 + i \left[ x \right]_1^3
\]

\[
= \left( \frac{9}{2} - \frac{1}{2} \right) + i(3 - 1) = 4 + 2i.
\]

Now we find \( \int_{C_1} z \, dz \) where \( C_1 \) is the straight line path from \( z = 3 + i \) to \( z = 3 + 3i \).

You will need to obtain expressions for \( u, v, dx \) and \( dy \). This is easily done by finding an appropriate expression for \( z \) along the path.

Then find limits on \( y \).
Along the path $z = 3 + i$, implying that $u = 3$ and $v = y$. Also $d \bar{z} = 0 + i \, dy$.

The limits on $y$ are:

$y = 1$ to $y = 3$

Now, continuing this example:

$$\int_{C_1} z \, dz = \int_{C_1} (u \, dx - v \, dy) + i \int_{C_1} (v \, dx + u \, dy)$$

$$= \int_1^3 -y \, dy + i \int_1^3 3 \, dy$$

$$= \left[ -\frac{y^2}{2} \right]_1^3 + i \left[ 3y \right]_1^3$$

$$= \left( -\frac{9}{2} + \frac{1}{2} \right) + i(9 - 3)$$

$$= -4 + 6i.$$

As a further example obtain $\int_{C_2} z \, dz$ where $C_2$ is the straight line path from $z = 1 + i$ to $z = 3 + 3i$. 

Your solution
We first need to find the equation of the line $C_2$ in the Argand plane. We note that both points lie on the line $y = x$ so the complex equation of the straight line is $z = x + i x$ giving $u = x$ and $v = x$. Also $dz = dx + idx = (1+i)dx$.

Next, we see that the limits on $x$ are $x = 1$ to $x = 3$. We are now in a position to evaluate the integral.

Therefore $\int_{C_2} z \, dz = i \int_1^3 x \, dx = i \left[ x^2 \right]_1^3 = i (9 - 1) = 8i$.

Note that this result is the sum of the integrals along $C$ and $C_1$. You might have expected this.

Example As a more intricate example consider the integral $\int_{C_1} z^2 \, dz$ where $C_1$ is that part of the unit circle going anticlockwise from the point $z = 1$ to the point $z = i$. See Figure 3.

![Figure 3](image)

Solution

First, note that $z^2 = (x + iy)^2 = x^2 - y^2 + 2xyi$ and $dz = dx + i \, dy$ giving

$$\int_{C_1} z^2 \, dx = \int_{C_1} [(x^2 - y^2) \, dx - 2xy \, dy] + i \int_{C_1} [2xy \, dx + (x^2 - y^2) \, dy].$$

This is obtained by simply expressing the integral in real and imaginary parts. These integrals cannot be evaluated in this form since $y$ and $x$ are related. Instead we re-write them in terms of the single variable $\theta$.

Note that on the unit circle:

$$x = \cos \theta, \ y = \sin \theta \quad \text{so that} \quad dx = -\sin \theta \, d\theta \quad \text{and} \quad dy = \cos \theta \, d\theta.$$
The expressions \((x^2 - y^2)\) and \(2xy\) can be expressed in terms of \(2\theta\) since
\[
x^2 - y^2 = \cos^2 \theta - \sin^2 \theta \equiv \cos 2\theta \quad 2xy = 2\cos \theta \sin \theta \equiv \sin 2\theta.
\]
Now as the point \(z\) moves from \(z = 1\) to \(z = i\) along the path \(C_1\) the parameter \(\theta\) changes from \(\theta = 0\) to \(\theta = \frac{\pi}{2}\).

Hence,
\[
\int_{C_1} f(z) \, dz = \int_0^{\frac{\pi}{2}} \left[ -\cos 2\theta \sin \theta \, d\theta - \sin 2\theta \cos \theta \, d\theta \right] + i \int_0^{\frac{\pi}{2}} \left[ -\sin 2\theta \sin \theta \, d\theta + \cos 2\theta \cos \theta \, d\theta \right].
\]

We can simplify these daunting-looking integrals by noting the trigonometric identities:
\[
\sin(A + B) \equiv \sin A \cos B + \cos A \sin B \quad \text{and} \quad \cos(A + B) \equiv \cos A \cos B - \sin A \sin B.
\]
We obtain (choosing \(A = 2\theta\) and \(B = \theta\) in both expressions):
\[
- \cos 2\theta \sin \theta - \sin 2\theta \cos \theta \equiv -(\sin \theta \cos 2\theta + \cos \theta \sin 2\theta) \equiv -\sin 3\theta.
\]
Also
\[
- \sin 2\theta \sin \theta + \cos 2\theta \cos \theta \equiv \cos 3\theta.
\]
Now we can complete the evaluation of our integral:
\[
\int_{C_1} f(z) \, dz = \int_0^{\frac{\pi}{2}} (-\sin 3\theta) \, d\theta + i \int_0^{\frac{\pi}{2}} \cos 3\theta \, d\theta
\]
\[
= \left[ \frac{1}{3} \cos 3\theta \right]_0^{\frac{\pi}{2}} + i \left[ \frac{1}{3} \sin 3\theta \right]_0^{\frac{\pi}{2}}
\]
\[
= (0 - \frac{1}{3}) + i \left( -\frac{1}{3} - 0 \right)
\]
\[
= -\frac{1}{3} - \frac{1}{3}i \equiv -\frac{1}{3}(1 + i).
\]

In the last example we are integrating \(z^2\) over a given path. We had to perform some intricate mathematics to get the value. It would be convenient if there was a simpler way to obtain the value of such complex integrals. What happens if we evaluate \(\left[ \frac{1}{3} z^3 \right]_1^i \)?

Your solution
It would seem that, by carrying out an analogue of real integration (simply integrating the
function and substituting in the limits) we can obtain the answer much more easily. Is this
coincidence?

If you return to the first example you will note:

\[
\left(\frac{1}{2}z^2\right)_{1+i}^{3+3i} = \frac{1}{2} \{ (3 + 3i)^2 - (1 + i)^2 \}
= \frac{1}{2} \{ 9 + 18i - 9 - 1 - 2i + 1 \}
= \frac{1}{2} (16i) = 8i,
\]

the result we obtained earlier.

We shall investigate these ‘coincidences’ in Section 26.5 on page 3.
As a variation on this example, suppose that the path \( C_1 \) is the entire circumference of the unit
circle travelled in an anti-clockwise direction.

What are the limits on \( \theta \)?

**Your solution**

\[ \quad \therefore \theta = 0 \text{ and } \theta = 2\pi \]

Hence \( \int_{C_1} f(z) \, dz = \int_0^{2\pi} (-\sin 3\theta) \, d\theta + i \int_0^{2\pi} \cos 3\theta \, d\theta. \)

Now evaluate the integral \( \int_{C_1} f(z) \, dz. \)

**Your solution**

\[ \therefore 0 = (0 - 0) + \left( \frac{\xi}{1} - \frac{\xi}{1} \right) = \]

\[ \left. \left. 0 \right|_{\xi}^{\xi} + \left. \left. \theta \xi \csc \xi \right|_{\xi}^{\xi} \right) = \zeta p(z) f \]
Is there an underlying reason for this result? We shall see in Section 26.5.

Another technique for evaluating integrals taken around the unit circle is shown in the next example, in which we need to evaluate

\[ \oint_C \frac{1}{z} \, dz \quad \text{where } C \text{ is the unit circle.} \]

Note the use of \( \oint \) since we have a closed path; we could have used this notation earlier.

Show that a point \( z \) on the unit circle can be written \( z = e^{i\theta} \) and hence find \( dz \) in terms of \( \theta \).

**Your solution**

\[
\theta p \theta = z \quad \text{so that} \quad \theta e^{i\theta} = \frac{\theta p}{z} \\
\text{Then, using De Moivre’s theorem, can be seen to be } \theta e^{i\theta} = z \quad \text{and hence} \quad \theta \sin = y, \quad \theta \cos = x
\]

Hence evaluate the integral \( \oint_C \frac{1}{z} \, dz \).

**Your solution**

\[
\oint_C \frac{1}{z} \, dz = \theta p \int_{\theta}^{0} = \theta p \theta e^{i\theta} \int_{\theta}^{0} \frac{0}{z} \, dz = \oint_{\theta}^{0} \int_{\theta}^{0} \frac{z}{z} \, dz
\]

We now quote one of the most important results in complex integration which incorporates the last result.
Key Point

If $n$ is a whole number (i.e. a positive or negative integer or zero) and $C$ is the circle centre $z = z_0$ and radius $r$, that is, it has equation $|z - z_0| = r$ then

$$\oint_C \frac{dz}{(z - z_0)^n} = \begin{cases} 0, & n \neq 1; \\ 2\pi i, & n = 1. \end{cases}$$

Note that the result is independent of the value of $r$.

Engineering Problem Posed

Application: Blasius’ Theorem. Finding the forces and moments due to the fluid flow past a cylinder.

Figure 4 shows a cross-section of a cylinder (not necessarily circular), whose boundary is $C$, placed in a steady non-viscous flow of an ideal fluid; the flow takes place in planes parallel to the $xy$ plane. The cylinder is out of the plane of the paper. The flow of the fluid exerts forces and turning moments upon the cylinder. Let $X, Y$ be the components, in the $x$ and $y$ directions respectively, of the force on the cylinder and let $M$ be the anticlockwise moment (on the cylinder) about the origin.

![Figure 4](image)

Blasius’ theorem (which we shall not prove) states that

$$X - iY = \frac{1}{2} i \rho \oint_C \left( \frac{dw}{dz} \right)^2 dz \quad \text{and} \quad M = \text{Re} \left\{ -\frac{1}{2} \rho \oint_C z \left( \frac{dw}{dz} \right)^2 dz \right\}$$

where $\text{Re}$ denotes the real part, $\rho$ is the (constant) density of the fluid and $w = u + iv$ is the complex potential (see Workbook 26.1) for the flow both of which are presumed known.
Engineering Problem Expressed Mathematically

We shall find $X, Y$ and $M$ if the cylinder has a circular cross-section and the boundary is specified by $|z| = a$.

Let the flow be a uniform stream with speed $U$.

Mathematical Analysis

Now, using a standard result, the complex potential describing this situation is:

$$w = U \left( z + \frac{a^2}{z} \right)$$

so that

$$\frac{dw}{dz} = U \left( 1 - \frac{a^2}{z^2} \right)$$

and

$$\left( \frac{dw}{dz} \right)^2 = U^2 \left( 1 - \frac{2a^2}{z^2} + \frac{a^4}{z^4} \right).$$

Using the Key Point earlier with $z_0 = 0$:

$$X - iY = \frac{1}{2} i \rho \oint_C \left( \frac{dw}{dz} \right)^2 dz = \frac{1}{2} i \rho U^2 \oint \left( 1 - \frac{2a^2}{z^2} + \frac{a^4}{z^4} \right) dz = 0.$$ 

Hence $X = Y = 0$. Also,

$$z \left( \frac{dw}{dz} \right)^2 = U^2 \left( z - \frac{2a^2}{z} + \frac{a^4}{z^3} \right).$$

The only term to contribute to $M$ is $-\frac{2a^2 U^2}{z}$.

Again using the Key Point above this leads to $-4\pi a^2 U^2 i$ and this has zero real part. Hence $M = 0$, also. The implication is that no net force or moment acts on the cylinder. This is not so in practice. The discrepancy arises from neglecting the viscosity of the fluid.

Exercises

1. Obtain the integral $\int_C zdz$ along the straight-line paths

   (a) from $z = 2 + 2i$ to $z = 5 + 2i$
   (b) from $z = 5 + 2i$ to $z = 5 + 5i$
   (c) from $z = 2 + 2i$ to $z = 5 + 5i$

2. Find $\int_C (z^2 + z)dz$ where $C$ is the part of the unit circle going anti-clockwise from the point $z = 1$ to the point $z = i$.

3. Find $\oint_C f(z)dz$ where $C$ is the circle $|z - z_0| = r$ for the cases

   (a) $f(z) = \frac{1}{z^2}$, $z_0 = 1$
   (b) $f(z) = \frac{1}{(z - 1)^2}$, $z_0 = 1$
   (c) $f(z) = \frac{1}{z - 1 - 1}$, $z_0 = 1 + i$
1. (a) Here $y$ is constant along the given path $z = x + 2i$, so that $u = x$ and $v = 2$. Also $d_y = 0$. Thus

$$
\int_C z \, dz = \int_C (u \, dx - v \, dy) + i \int_C (v \, dx + u \, dy) = \int_5^2 x \, dx + i \int_5^2 2 \, dx = \left[ \frac{x^2}{2} \right]_5^2 + i \left[ 2x \right]_5^2 = \left( \frac{25}{2} - \frac{1}{2} \right) + i \left( 10 - \frac{6}{2} \right) = 21 + 6i.
$$

(b) Here $dx = 0$, $v = y$, $u = 5$. Thus

$$
\int_C z \, dz = \int_C (-y) \, dy + i \int_C 5 \, dy = \left[ -y^2 \right]_5^2 + i \left[ 5y \right]_5^2 = \left( -\frac{25}{2} + \frac{4}{2} \right) + i \left( 25 - 10 \right) = -\frac{21}{2} + 15i.
$$

(c) $z = x + ix$, $u = x$, $v = x$, so $dz = (1 + i) \, dx$, so

$$
\int_C z \, dz = \int_C (x \, dx - x \, dx) + i \int_C (x \, dx + x \, dx) = \int_C 2i \, dx = 2i \left[ x \right]_5^2 = 21i.
$$

Note that the result in (c) is the sum of the results in (a) and (b).

2. \[
\int_C (z^2 + z) \, dz = \left[ \frac{z^3}{3} + \frac{z^2}{2} \right]_1^1 = \frac{1^3}{3} + \frac{1^2}{2} - \left( \frac{1^3}{3} + \frac{1^2}{2} \right) = -\frac{4}{3} - \frac{1}{3} = -\frac{5}{3}.
\]

3. Using the Key Point on page 9, we have (a) 0, (b) 0, (c) $2\pi i$. Note that in all cases the result is independent of $r$.

$$\frac{z}{1 - z} - \frac{z}{1 + z} = \left( \frac{z}{1} + \frac{z}{z} \right) - \left( \frac{z}{1} + \frac{z}{z} \right) = \frac{z}{z} = z \frac{z + z^2}{z^2 - 1} = \frac{z^3}{z^2 - 1} = z \left( \frac{z^2 - 1}{z^2 - 1} \right) = z \left( \frac{1}{z} \right) = \frac{z}{z} = 1.$$
